ABSTRACT OF THE DISCLOSURE

A mobile communication system can limit
interference from mobile stations under an adjacent
base station to a minimum. In response to a time slot
assignment request, a time slot management section
compares available time slots stored in an assignable
time slot database with a priority table of the time
slot assignment, which is stored in the priority
database, and assigns the time slots in accordance
with the compared result. After completing the
assignment, it stores a table of the frame state
indicating new available time slots into the
assignable time slot database.
